Declaration of Authorship

I, Josef Šanda, declare that this thesis titled, “Voice-Enabled Smart Home Modules” and the work presented in it are my own. I confirm that:

- This work was done wholly or mainly while in candidature for a research degree at this University.
- Where any part of this thesis has previously been submitted for a degree or any other qualification at this University or any other institution, this has been clearly stated.
- Where I have consulted the published work of others, this is always clearly attributed.
- Where I have quoted from the work of others, the source is always given. With the exception of such quotations, this thesis is entirely my own work.
- I have acknowledged all main sources of help.

Signed:

Date:

1.2 Thesis Objectives

1.3 Thesis Outline

Chapter 2

Dialog Systems

2.1 Automatic Speech Recognition

ASR (Automatic Speech Recognition) is a way of converting sound into text.

Sound is nothing more than vibrations of the air that we humans are trained exceptionally well to decode. Moreover, now, we are teaching our computers how to do this. In the beginning, we have a stream of words that a person has uttered. The sound is picked up by a microphone and converted to a digital signal through a sound card, which means a stream of ones and zeroes.

One of the possible approaches in ASR modelling is, for example, at the level of phonemes or the level of whole words. We will only give an example here at the phoneme level, as the other approaches are very similar.

The first step the ASR system do is process the sound. It steps the sound to have chunks of speech (shown in Fig. 2.1) that can be worked with and that can be mapped to letters. These chunks are called phones.

Figure 2.1: Chunked speech signal

The part of ASR responsible for mapping sound to phones is called the *acoustic model* as a set of building blocks, boxes which contain models for all phones in a given language as showing in Fig. 2.2.

Figure 2.2: Phones boxes

There are boxes labelled, for example, A, B, C, depending on which phones are used in the particular language. On top of that, part of this construction set is also contextual probabilities. It means how likely a phone is to follow another. The acoustic model's task is to guess which phones have been pronounced and how they combine into a word. The acoustic model processes the sound and compares it to the models of individual phones from its boxes. Since speech is very complex in a real scenario, the chunks that a person uttered will be similar to more than one box. The acoustic model takes this into account and also looks at the neighbouring chunks and their contextual probabilities. For example, in the string "HELLO", the second phoneme that a person uttered might have been E. However, it also could have been ə, A or even I, with different degrees of certainty. The next phoneme is probably L, but it also could be R. There are different probabilities of these phones in context, for example, H followed by E is more likely, at least in English, than H followed by I. The ASR system combines these bits of information and outputs the most likely result - a string of phones. (Stanislav, 2020)

The next step is to convert it into words. Nevertheless, this part can be tricky because the ASR does not know when a word starts or ends. Contrary to popular belief, there are no pauses between words in fluent speech. This particular string "heloumaj..." of phones can constitute several different phrases, for example, "hell oh my nay miss" or "hello mine aim is", or "hello my name is". The part of ASR responsible for mapping phones to words and phrases is called the language model.

Hidden Markov Models are widely used for the statistical approach for automatic speech recognition. Suppose that $W = \{w_1, w_2, \dots, w_N\}$ is a sequence of words, and $O = \{o_1, o_2, \dots, o_N\}$ is a sequence of phones. These sequences are taken with a period of 10 ms for segments of speech of length from 20 to 40 ms. The Bayes Theorem for conditional probability is used to figure out which phones have been pronounced and how they combine into a word.

$$W' = \underset{w}{\operatorname{argmax}} P(W | O) = \underset{w}{\operatorname{argmax}} \frac{P(W)P(O | W)}{P(O)} \quad (2.1)$$

where $P(W)$ is the a priori probability of word W , $P(O|W)$ is the probability that the sequence of phones O will be generated under the conditions of pronouncing the sequence of words W , $P(O)$ is the a priori probability of the sequence of phones O .

Since the probability $P(O)$ is independent of the sequence of words W , it is possible to modify the equation into the form:

$$W' = \underset{w}{\operatorname{argmax}} P(W | O) = \underset{w}{\operatorname{argmax}} P(W)P(O | W) \quad (2.2)$$

2.2 Automatic Speech Synthesis

The task of generating speech out of text information has originally two approaches:

1. concatenative (unit selection);
2. statistical parametric.

With concatenative synthesis is based on sequential combining of short prerecorded samples of speech. These samples can be stored in a database in the form of whole sentences, phrases, words and different phonemes. It depends on the application of the solutions. Building the unit selections synthesis model consists of three steps:

1. Recording of whole selected speech units in no possible context.
2. Labelling segmentation of units.
3. Choosing the most appropriate units.

The concatenated method is the most straightforward approach to speech generation. Disadvantages include the requirement to have ample storage for recorded units and an ability to apply various changes to a voice.

Statistical parametric synthesis consists of two parts, as shown in Fig. 2.3. The training step's approach is to extract excitation parameters like fundamental frequency and dynamic features, and spectral parameters from the speech database. Then we estimate them using one of the statistical models. The HMM is the most widely used for this task. It should be noted that HMM is conscious dependent it means that in this step, in addition to phonetic context, linguistic and prosodic context is taken into account. In the synthesis part, at first given sentence is converted into points with a dependent label sequence, and then their chance HMM is constructed according to this sequence. Next, spectrum and excitation parameters are generated from the utterance HMM, and finally, speech waveforms are synthesized from these parameters using excitation generation and the speech synthesis filter. The advantages of the statistical parametric approach are:

1. Small footprint

2. No need to store speech waveforms, only statistics language independence
3. Flexibility in changing voice characteristics speaking styles and emotions.

The most noticeable drawback is the quality of a synthesized speech.

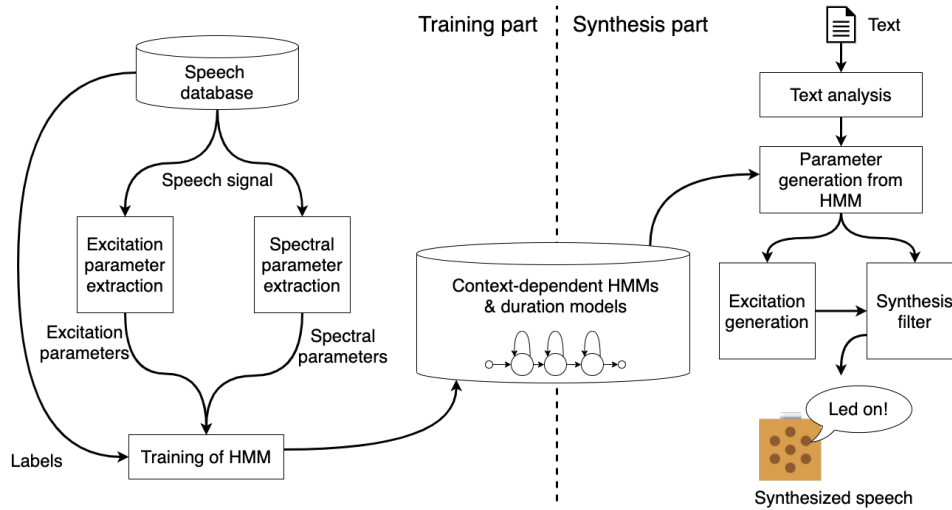

Figure 2.3: Synthesis model

2.3 KKY SpeechCloud

SpeechCloud is a system that connects ASR and TTS systems operating together via one interface. It is then possible to use these systems by many applications simultaneously through this interface. An independent instance is created for each dialogue system, allowing a client to create a characteristic language model, send a speech record to recognize, and receive the synthesized speech.

SpeechCloud provides the same services to all clients, unless otherwise limited or specified. Each client should have the same functions, but each device, experiment or project is separated from the others, so the results are not affected by the unwanted intervention.

The architecture of SpeechCloud and connection to client briefly visualizing Fig. 2.4. SpeechCloud using the module SCAPIServer as a primary point for reach a connection with the client application. Thus, the module negotiates with the client the configuration for client applications, control communication channel, and authentication of a session. The SCAPIServer then provides these pieces of information to other modules. The SIPSwitch module mediates the audio data transfer service between the SCWorker component and the client application. One instance of the SCWorker component is reserved for each client that holds one ASR and TTS instance. The SCWorker component has access to a TCP/IP network connection to collect additional data sources.

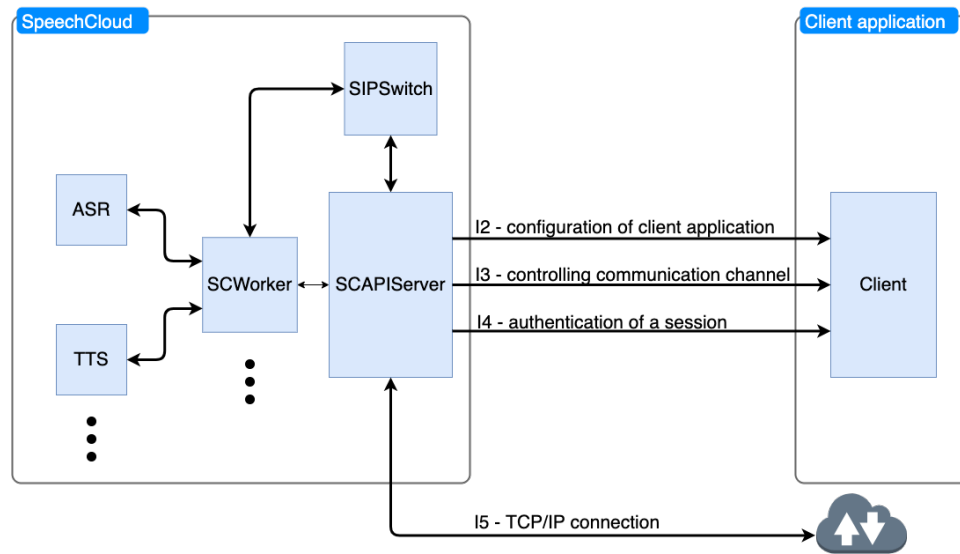

Figure 2.4: SpeechCloud schema

Solving the subject of the connection and transmission of data to the SpeechCloud via Internet communication protocols is not the content of this work hence are used ready-made software components.

Chapter 3

Backend

Own engine running on Raspberry Pi 4 has been developed and serves as the backend for the project. The whole engine is coded in Python, and adheres to the following principles:

- *Simplicity*: write a straightforward code that is easily understandable for later rewriting.
- *Modifiability*: write a code with the ability to admit changes due to a new requirement or detect an error that needs to be fixed.
- *Modularity*: write a well-encapsulated code of modules, which do particular, well-documented functions.
- *Robustness*: write a code focusing on handling unexpected termination and unexpected actions.

3.1 Diagram description

This section briefly describes the architecture of the engine that is figured on a diagram - see Fig. 3.1.

Figure 3.1: Project architecture

Engine uses tools like MQTT, MongoDB, Tornado web server that is described later. Each of them runs in its thread and concurrently. These

tools create a basis for modules and mediate main functionalities such as database, web server and communication.

The engine is designed to easily remove, add or update any mutually independent modules that define functions used by a user interface. Each module is described in the Chap. 4.

The engine also contains a separate block for *logic*. This block captures a command from the VoiceKit or keyboard interface, then browsing a pre-defined list of each module's commands and determines the best match for the user voice command or command written on the keyboard. If it does not find the voice command in lists, it replies that the command has not found with the recognized command.

3.2 Database

MongoDB is an open-source document database built upon a NoSQL database and written in C++. Database's horizontal, scale-out architecture support vast volumes of both data and traffic. One document can have others embedded in itself, and there is no need to declare the structure of documents to the system - documents are self-describing.(Jayaram, 2020)

Before using this type of database, we have to be familiar with different terminology compare to traditional SQL databases:

SQL Server	MongoDB
Database	Database
Table	Collection
Index	Index
Row	Document
Column	Field
Joining	Linking & Embedding
Partition	Sharding (Range Partition)
Replication	ReplSet

Table 3.1: MongoDB terminology

We use this type of database because it is famous for its use in agile methodologies, and the project tends to enlarge in the future. The main benefits are:

- MongoDB is easy to scale.
- Schema-less database: we do not need to design the database's schema because the code we write defines the schema, thus saves much time.
- The document query language supported by MongoDB is simplistic as compared to SQL queries.

- There is no need for mapping application's objects to database's objects in MongoDB.
- No complex joins are needed in MongoDB. There is no relationship among data in MongoDB.
- Because of using JSON¹ format to store data, it is effortless to store arrays and objects.
- MongoDB is free to use. There is no cost for it.
- MongoDB is simple to set up and install.

For adding a new field, the field can be created without affecting all other documents in the collection, without updating a central system catalog, and without taking the system offline.

In the project, we save all incoming messages from MQTT to MongoDB to a collection based on a name of interest module.

3.3 Communication

Communication is the backbone of the whole project among several devices over the internet. Therefore, it had to be found robust, scalable, and cost-effective protocols that transmit messages and data securely. Based on the survey, we choose three protocols that, in combination, satisfy all our requirements, and we will delve deeper into them in the following sections.

3.3.1 MQTT

MQTT is a standardized protocol by the OASIS MQTT Technical Committee used for message and data exchange. The protocol is designed specifically for the Internet of Things. The protocol is developed in vast language diversity from low-level to high-level programming language and designed at light versions for low-performance devices. Hence, it suits our use-case perfectly because each module possesses tons of various devices with limited resources that are already included or will arise later on. (Malý, 2016)

¹JavaScript Object Notation

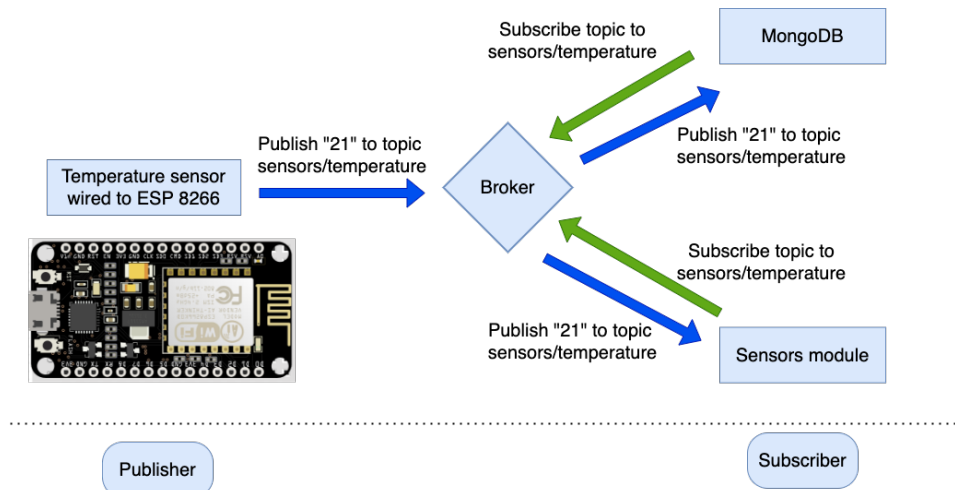

Figure 3.2: MQTT publisher/subscriber pattern

The design principles are to minimize network bandwidth and device resource requirements whilst also attempting to ensure reliability and some degree of assurance of delivery. The protocol determines errors by TCP and orchestrates communication by the central point - broker. The protocol architecture uses a publish/subscribe pattern (also known as pub/sub) shown in Fig. 3.2, which provides an alternative to traditional client-server architecture. Architecture decouples publishers and subscribers who never contact each other directly and are not even aware that the other exist. The decoupling give us the following advantage:

- *Space decoupling*: publisher and subscriber do not need to know each other.
- *Time decoupling*: publisher and subscriber do not need to run at the same time.
- *Synchronization decoupling*: operations on both components do not need to be interrupted during publishing or receiving.

When the publisher sends his message, it is handled by the broker who filters all incoming messages and distributes them to accredited subscribers. The filtering is based on topic or subject, content and type.

In the case of MQTT, the filtering is subject-based and therefore, every message including a subject or a topic. The client subscribes to the topics he is interested in, and the broker distributes the messages accordingly as shown in Fig. 3.3.

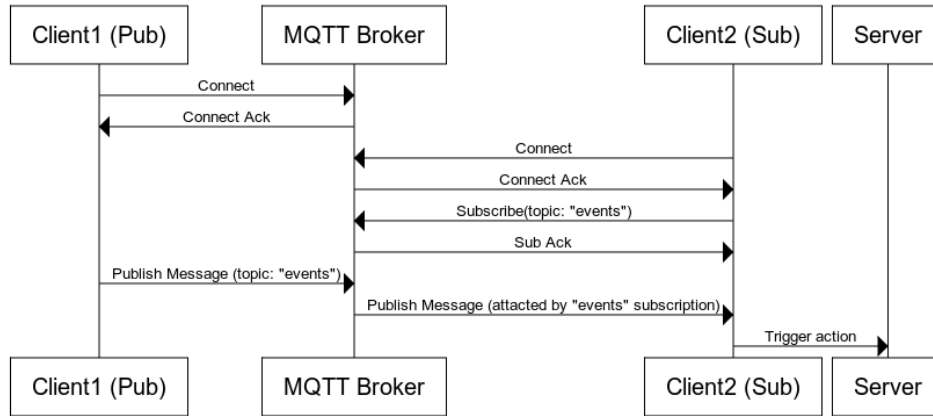

Figure 3.3: Diagram illustrating how communication in MQTT flow.

The topics are generally strings with a hierarchical structure that allow different subscription levels. It is feasible to use wildcards to subscribe, for example, `sensors/#` to receive all messages related to the sensors, for example, `sensors/temperature` or `sensors/illuminance`.

The MQTT protocol has the Quality of Service (QoS) levels essential to any communication protocol. The level of QoS can be specified for each message or topic separately according to its importance.

In MQTT, there are 3 QoS levels:

- **QoS 0:** This level is often called "fire and forget" when a message is not stored and retransmitted by a sender.
- **QoS 1:** It guarantees that a message is delivered at least one time to the receiver. The message is stored on a sender until it gets a PUBACK packet from a receiver.
- **QoS 2:** It is the highest level, and it guarantees that each message received only once by the intended recipients.

It is vital to mention MQTT has the feature retained messages that are mechanisms where the broker stores the last retained message for a specific topic. This feature allows a client does not have to wait until a new message is published to know the last known status of other devices.

3.3.2 WebSocket

In this work, WebSockets are used to provide communication between the client and the engine. WebSocket provides a low-latency, persistent, full-duplex connection between a client and server over TCP. The protocol is chiefly used for a real-time web application because it is faster than HTTP concerning more transfers by one connection. The protocol belongs to the stateful type of protocols, which means the connection between client and server will keep alive until either client or web server terminate it. The protocol fits for us in use between client and web server in case of real-time response. (Wang, Salim, and Moskovits, 2013)

The main benefits are:

- *Persistent*: After an initial HTTP handshake, the connection keeps alive using a ping-pong process, in which the server continuously pings the client for a response. It is a more efficient way than establishing and terminating the connection for each client request and server response. Server terminating connection after an explicit request from the client, or implicitly when the client goes offline.
- *Secure*: WebSocket Secure uses standard SSL and TLS encryption to establish a secure connection. Although we do not pursue this issue in our work, it is a valuable feature to add later.
- *Extensible*: Protocol is designed to enabling the implementation of subprotocols and extensions of additional functionality such as MQTT, WAMP, XMPP², AMQP³, multiplexing and data compression. This benefit makes WebSockets a future-proof solution for the possible addition of other functionalities.
- *Low-latency*: WebSocket significantly reduces each message's data size, drastically decreasing latency by eliminating the need for a new connection with every request and the fact that after the initial handshake, all subsequent messages include only relevant information.
- *Bidirectional* - This enables the engine to send real-time updates asynchronously, without requiring the client to submit a request each time, as is the case with HTTP.

We will apply this protocol for transfer between clients such as VoiceKit, keyboard or web interface and engine in case of real-time response.

3.3.3 REST

In other cases like fetching data only once or data that is not required very frequently, we use RESTful web service on a web server. This service enables us to transfer a lightweight data-interchange format JSON trivially and reliably - see Fig. 3.4. We use a standard GET REST request on a defined URI and then decode it like JSON for fetching data.

²**Extensible Messaging and Presence Protocol** - messaging and presence protocol based on XML and mainly used in a near-real-time exchange of structured data.

³**Advanced Message Queuing Protocol** - an open standard application layer protocol for message-oriented middleware.

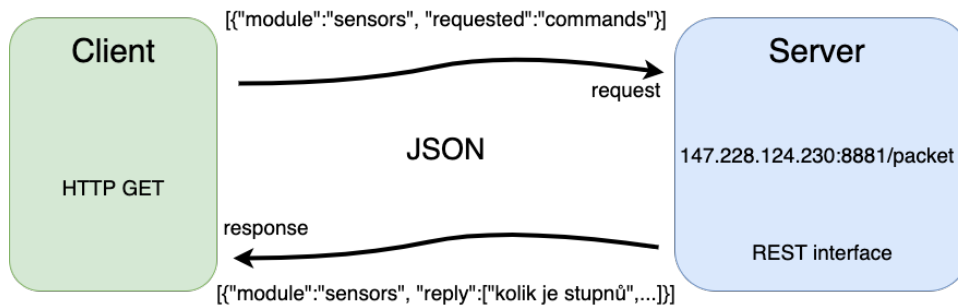

Figure 3.4: REST principle

3.4 Controllers

3.4.1 Keyboard

The keyboard is a python script with a particular purpose for developing new voice commands. This script opens up a CLI built upon a voicehome controller. The developer can quickly type a voice command with high accuracy through the command-line and debug the command thoroughly in various forms.

3.4.2 VoiceKit

VoiceKit is a building kit made by Google that lets users create their natural language processor and connect it to the Google Assistant or Cloud Speech-to-Text service. By pressing a button on top, users can ask questions and issue voice commands to their programs. All of this fits in a handy little cardboard cube powered by a Raspberry Pi. (Voice Kit)

3.4.3 Website

The second interface next to the already mentioned VoiceKit is a website. The webserver is implemented in Python using the Tornado framework.

Chapter 4

Modules

4.1 Lights

This module opens up to the user a simple way how can control lights by voice. The user not only turns on, off or blinks lights but can also identify the development boards by lighting a onboard LED on a specific board. The module keeps in memory a list of all lights with their current status and detailed description.

The onboard LEDs are mounted on the board from the factory on pin 2. The other lights have their specific wiring, but one LED is prepared for demonstration purposes, which by our definition is located in the living room and is wired according to the diagram in Fig. ***.

4.1.1 Voice commands

The module responds to the following questions:

- Turn on all the onboard LEDs

Voice commands

- "Rozsviť všechny vývojové desky."
- "Rozsviť všechny vestavěné ledky."

Reply

- Module confirm each light separately - "Vývojová deska jedna je rozsvícena.", "Vývojová deska dva je rozsvícena.", etc.

- Turn off all the onboard LEDs

Voice commands

- "Zhasni všechny vývojové desky."
- "Zhasni všechny vestavěné ledky."

Reply

- Module confirm each light separately - "Vývojová deska jedna je zhasnuta.", "Vývojová deska dva je zhasnuta.", etc.

- Turn on the light 1

Voice commands

- "Zapni obýváku světlo."
- "Rozsviť obýváku světlo."
- "Zapni obývacím pokoji světlo."
- "Rozsviť obývacím pokoji světlo."

Reply

- "Světlo v obývacím pokoji rozsvíceno."

- Turn off the light 1

Voice commands

- "Vypni obýváku světlo."
- "Zhasni obýváku světlo."
- "Vypni obývacím pokoji světlo."
- "Zhasni obývacím pokoji světlo."

Reply

- "Světlo v obývacím pokoji zhasnuto."

- Turn on the onboard LED number 1

Voice commands

- "Rozsviť vestavěnou ledku vývojové desky číslo jedna."
- "Rozsviť vývojovou desku číslo jedna."

Reply

- "Vývojová deska číslo jedna rozsvícena."

- Turn off the onboard LED number 1

Voice commands

- "Zhasni vestavěnou ledku vývojové desky číslo jedna."
- "Zhasni vývojovou desku číslo jedna."

Reply

- "Vývojová deska číslo jedna zhasnuta."

- Turn on the onboard LED number 2

Voice commands

- "Rozsviť vestavěnou ledku vývojové desky číslo dva."
- "Rozsviť vývojovou desku číslo dva."

Reply

- "Vývojová deska číslo dva rozsvícena."

- Turn off the onboard LED number 2

Voice commands

- "Zhasni vestavěnou ledku vývojové desky číslo dva."
- "Zhasni vývojovou desku číslo dva."

Reply

- "Vývojová deska číslo dva zhasnuta."

- Turn on the onboard LED number 3

Voice commands

- "Rozsviť vestavěnou ledku vývojové desky číslo tři."
- "Rozsviť vývojovou desku číslo tři."

Reply

- "Vývojová deska číslo tři rozsvícena."

- Turn off the onboard LED number 3

Voice commands

- "Zhasni vestavěnou ledku vývojové desky číslo tři."
- "Zhasni vývojovou desku číslo tři."

Reply

- "Vývojová deska číslo tři zhasnuta."

- Voicekit answer which lights are turned on

Voice commands

- "Která světla svítí."

Reply

- "Aktuálně nejsou rozsvícena žádná světla."
- "Aktuálně jsou rozsvícena tyto světla první ESP, druhé ESP.."

4.1.2 Messages structure

The engine uses for maintain lights following topics and messages:

- "voicehome/lights/command" - to turn the light on/off

```

1 {
2   "ID":1,
3   "type":"ESP_onboard",
4   "set":0
5 }
```

Part of Code 4.1: Structure of JSON message to turn on/off the light in module *Lights*

- "voicehome/lights/state/command" - to ask the light for state

```

1 {
2   "ID":1,
```

```

3     "type": "ESP_onboard"
4 }

```

Part of Code 4.2: Structure of JSON message to asking for the state of the light in module *Lights*

- "voicehome/lights/state/receive" - to receive state of the light

```

1 {
2     "type": "light",
3     "state": 0,
4     "ID": 1
5 }

```

Part of Code 4.3: Structure of JSON message to receive state of the light in module *Lights*

4.2 Time

This module provides commands for manipulation with the time, such as asking for time, date, set timer. The module does not communicate with other devices. The module's functions exploit system information and information available on the Internet. To reach this information from the web is used technique call web scraping that can run the web site and suck desired pieces of information from this site. A simple example of this technic is shown in code part 4.4

```

1     from selenium import webdriver
2     from selenium.webdriver.chrome.options import Options
3
4     self.driver = webdriver.Chrome(executable_path='/usr/bin/
        chromedriver')
5     self.driver.get('www.seznam.cz')

```

Part of Code 4.4: Simple example how to do web scraping in Python

4.2.1 Voice commands

The module responds to the following questions:

- Send command to ask the server for the current time.

Voice commands

- Kolik je hodin?
- Čas

Reply

- Právě je pět hodin dvacet minut a pět sekund.

- Send command to ask the server for the current day of year.

Voice commands

- Kolikátého dnes je?
- Datum

Reply

- Dnes je 4. 5. 2021

4.3 System

The system module provides the user commands to test the functionality and adjust some settings of the engine. The module communicates primarily with the engine, but it is possible to establish this communication with other devices. Like other technology, the module uses the MongoDB library from python to test the engine's database.

4.4 Sensors

The sensors module provides the user commands to communicate directly with sensors wired to the ESP development board or ask for statistics information such as average. The sensors connected to the module are bme280, ds18b20 and tsl2591. The module uses the Python library to obtain old data from the MongoDB database to calculate statistical data.

4.5 Weather

The weather module provides the user commands to answer questions about the weather. The module's functions exploit the information available on the Internet. By preprocessing the information from the Internet and replating characters like "°C" to "stupňů" or "-" to "mínus", we can then send fully synthesizable text to SpeechCloud and answer the question to the user. To reach this information from the web is used technique call web scraping that can run the web site and suck desired pieces of information from this site. Preprocessing the information uses the technique regex and essential functions such as finding text and selecting text — a simple example of how regex is used shown in code part 4.5.

```
1 import re
2
3 regex_patterns_forecast_monday = '^(Předpověď na pondělí
  \(\00-24\))'
4 for num_line in range(8, len(whole_forecast)):
5     match = re.search(regex_patterns_forecast_monday,
6                       whole_forecast[num_line][:30])
7     if match:
8         forecast = results[num_line].split('\n')[1]
9         self.reply('Server chmi.cz předpovídá na pondělí. ' +
                    forecast)
```

```
10         break
11 else:
12     self.reply('Nebylo možno získat data ze serveru chmi.cz')
13     return
```

Part of Code 4.5: Simple example how to use regex in
Python
